Proximal femoral fractures. Proximal femoral fractures are a subset of fractures that occur in the hip region. They tend to occur in older patients, and in those who have osteoporosis. In this group of patients, fracture is usually the result of low-impact trauma although, in younger patients they are usually victims of high-impact trauma, usually during a car accident.

Proximal femoral fractures are typically associated with osteoporosis in the elderly. In the elderly, fractures of the proximal femur are typically associated with a condition called osteoporosis. Osteoporosis makes bones weaker and more likely to break, and a broken hip is one of the most common complications.

Proximal femoral fractures present unique challenges for anaesthetic departments, involving the peri-operative care of large numbers of older patients with significant co-morbidities. Despite guidance since the early 1990s concerning best practice management for these vulnerable patients, there remains considerable variation in models of peri-operative care, rehabilitation and orthogeriatric input.
