A linear differential equation or a system of linear equations such that the associated homogeneous equations have constant coefficients may be solved by quadrature, which means that the solutions may be expressed in terms of integrals. This is also true for a linear equation of ...

Linear differential equation - Wikipedia

A Partial Differential Equation commonly denoted as PDE is a differential equation containing partial derivatives of the dependent variable (one or more) with more than one independent variable. A PDE for a function $u(x_1, \dots, x_n)$ is an equation of the form The PDE is said to be linear if f is a linear function of u and its derivatives.

In contrast, a partial differential equation (PDE) has at least one partial derivative. Here are a few examples of PDEs: DEs are further classified according to their order. This classification is similar to the classification of polynomial equations by degree.

Overview In this module we will study linear partial differential equations, we will explore their properties and discuss the physical interpretation of certain equations and their solutions. We will learn how to solve first order equations using the method of characteristics and second order equations using the method of separation of variables.

0. Similarly, for $u(x, y) = e^y \sin x$, we have $u_x = e^y \cos x$, $u_y = e^y \cos x$, $u_{xx} = -e^y \sin x$, and $u_{yy} = e^y \sin x$. Therefore, $u_{xx} + u_{yy} = -e^y \sin x + e^y \sin x = 0$, so the equation is satisfied for both functions. Clear $[u]_{x,y} = \text{Exp}[y] \text{Sin}[x]; D[u]_{x,y}, \{x, 2\} + D[u]_{x,y}, \{y, 2\} = 0$.

Partial Differential Equations

Partial differential equations (PDEs) of hyperbolic/nearly hyperbolic type are of fundamental importance in many areas of applied mathematics and engineering, particularly for applications arising in fluid dynamics and electromagnetics. Typically, solutions to these types of equations exhibit localized phenomena, such as propagating discontinuities and sharp transition layers, and their reliable numerical approximation represents a challenging computational task.

$u(x) = \exp(-\int a(x)dx)$. Multiplying the left side of the equation by the integrating factor $u(x)$ converts the left side into the derivative of the product $y(x)u(x)$. The general solution of the differential equation is expressed as follows: $y = u(x) \int f(x)dx + C u(x)$, where C is an arbitrary constant.
